Abstract

In this paper, we present a thing.

1 Introduction

Write the introduction

2 Background

Throughout this paper, we let $\mathbb{G}$ denote a group of prime order q, with generators G and H. Let $\mathbb{F}_q$ denote the scalar field associated with this group, and let $\mathbb{Z}/(q)$ denote the additive group of elements in this field.

We make heavy use of group homomorphisms throughout this paper. We let

$$\varphi(P_1, \ldots, P_m) : \mathbb{A} \to \mathbb{B}$$

denote a homomorphism from $\mathbb{A}$ to $\mathbb{B}$, parameterized by some public values $P_1, \ldots, P_m$. Commonly $\mathbb{A}$ will be a product of several groups $\mathbb{G}_1, \ldots, \mathbb{G}_n$, in which case we'd write:

$$\varphi(P_1, \ldots, P_m)(x_1, \ldots, x_n)$$

to denote the application of φ to an element $(x_1, \ldots, x_n)$ of the product group. We also often leave the public values P_i implicit.

2.2 Sigma Protocols

2.3 Maurer's φ-Proof

In [Mau09], Maurer generalized Schnorr's sigma protocol for knowledge of the discrete logarithm [Sch90] to a much larger class of relations. In particular, Maurer provided a sigma protocol for proving knowledge of the pre-image of a group homomorphism φ. We denote this protocol as a "φ-proof", and recapitulate the scheme here.

Given a homomorphism $\varphi : \mathbb{A} \to \mathbb{B}$, and a public value $X \in \mathbb{B}$, the prover wants to demonstrate knowledge of a private value $x \in \mathbb{A}$ such that $\varphi(x) = X$. The prover does this by means of Protocol 2.1:

Protocol 2.1: φ-Proof

Prover	**Verifier**
knows $x \in \mathbb{A}$	public $X \in \mathbb{B}$

$k \xleftarrow{R} \mathbb{A}$
$K \leftarrow \varphi(k)$

$$\xrightarrow{\quad K \quad}$$

$$c \xleftarrow{R} \mathbb{Z}/(p)$$

$$\xleftarrow{\quad c \quad}$$

$s \leftarrow k + c \cdot x$

$$\xrightarrow{\quad s \quad}$$

$$\varphi(s) \overset{?}{=} K + c \cdot X$$

Here, p is chosen such that $\forall B \in \mathbb{B}.\ p \cdot B = 0$. In practice, we'll set $p = q$, which will work perfectly for the groups we use, which are all products of $\mathbb{G}$ or $\mathbb{Z}/(q)$.

Claim 2.1. Protocol 2.1 is a valid sigma protocol.

Completeness follows directly from the fact that φ is a homomorphism.

For the HVZK property, the simulator $\mathcal{S}(X, c)$ works by generating a random $s \xleftarrow{R} \mathbb{A}$, and then setting $K := \varphi(S) - c \cdot X$.

Finally, we prove 2-extractability. Given two verifying transcripts (K, c, s) and (K, c', s') sharing the first message, we extract a value $\hat{x}$ satisfying $\varphi(\hat{x}) = X$ as follows:

$$\varphi(s) - c \cdot X = K = \varphi(s') - c' \cdot X$$
$$\varphi(s) - \varphi(s') = c \cdot X - c' \cdot X$$
$$\frac{1}{c - c'} \cdot \varphi(s - s') = X$$
$$\varphi\left(\frac{s - s'}{c - c'}\right) = X$$

2

Thus, defining $\hat{x} := (s-s')/(c-c')$, we successfully extract a valid pre-image.

We conclude that the protocol is a valid sigma protocol.

■

Maurer's protocol can also work even in the case where the order of the groups are not known, but this makes the challenge generation a bit more complicated, and we don't need this functionality in this work.
